

Microbiology Nuts & Bolts: Session 4: Primary Care Infections

Aims & Objectives

- To know how to diagnose and manage life-threatening infections
- To know how to diagnose and manage common infections
- To understand how to interpret basic microbiology results
- To have a working knowledge of how antibiotics work
- To understand the basics of infection control

www.microbiologynutsandbolts.co.uk

- Many consultations in primary care are for potential infections, where it can be difficult to distinguish those that need treating with antibiotics and those which do not
- It is important to know how to diagnose and manage common infections so that complications do not occur and patients get better as quickly as possible
- Knowing about antibiotics ensures the correct ones are used for the correct indications, prevents prescribing errors and keeps patients safe
- Everyone working in a healthcare setting has a responsibility to protect patients from harm including cross infection from other patients

Mary

- 70 years old
- Presents with cough, increasing shortness of breath, increasingly purulent sputum
- Past Medical History
 - Hypertension, Type 2 Diabetes, Chronic Obstructive Pulmonary Disease
- On examination
 - Temperature 37.5 °C
 - Crepitations at the right base
 - B.P. 140/85, H.R. 98 bpm

How should Mary be managed?

www.microbiologynutsandbolts.co.uk

- This is a common history both in primary and secondary care, both in terms of presenting symptoms as well as co-morbidities
- If taken correctly her temperature is the upper end of normal and her cardiovascular system observations are normal
- The presence of crepitations on auscultation indicates interstitial changes such as fibrosis or fluid, not consolidation
- Given her past medical history of chronic obstructive pulmonary disease, shortness of breath but no symptoms of pneumonia it would be reasonable to treat Mary for a non-pneumonic exacerbation of COPD

Differential Diagnosis

British Thoracic Society Guidelines for Community Acquired Pneumonia (CAP)

- Cough PLUS one other respiratory tract symptom
 - Shortness of breath
 - Purulent sputum
 - Chest pain
- New focal chest signs
 - Reduced expansion
 - Bronchial breathing
 - Dull percussion
 - T-tenderness
- Systemic symptoms
 - Fever, sweats, chills, aches & pains
- No other explanation

Exacerbation of COPD

- Shortness of breath
- Purulent sputum
- ↑ Amount of sputum

www.microbiologynutsandbolts.co.uk

- The British Thoracic Society (BTS) have published guidelines that cover the diagnostic criteria of community acquired pneumonia in primary care as well as exacerbations of COPD

- Diagnosed with Exacerbation of COPD
- Sputum
- Prescribed Amoxicillin PO
- Planned Chest X-ray if not improving

www.microbiologynutsandbolts.co.uk

- The treatment with Amoxicillin is reasonable and would cover the common bacteria which cause exacerbation of COPD which are covered later
- Alternative treatments could be PO Clarithromycin or PO Doxycycline

Appearance of sputum

- Salivary
 - Spit not phlegm, risk of contamination
- Mucoid
 - Upper respiratory tract specimen, no evidence of inflammation
 - Beware neutropaenic patients
- Purulent
 - Pus, indicates inflammation not infection
- Blood stained
 - May indicate infection but not pathognomic

www.microbiologynutsandbolts.co.uk

- As with other tests it is important to have a system for looking at microbiology results
- Microbiology results should be looked at in the following order if available:
 - Appearance
 - Microscopy
 - Culture
- For sputum results the appearance gives guidance on the likelihood of any cultured bacteria being from the upper respiratory tract or not
- Too many patients get treated for what is essentially normal flora and this is a mistake!

Causes of Respiratory Infections

Community Acquired Pneumonia <ul style="list-style-type: none"> • Viruses: <ul style="list-style-type: none"> - RSV - Influenza - Parainfluenza - Adenovirus • Bacteria: <ul style="list-style-type: none"> - S. pneumoniae - H. influenzae - S. aureus - H. pertussis - C. pneumoniae - L. pneumophila - P. aeruginosa (if COPD) - M. tuberculosis 	Exacerbation of COPD <ul style="list-style-type: none"> • Viruses: <ul style="list-style-type: none"> - RSV - Influenza - Parainfluenza - Adenovirus • Bacteria: <ul style="list-style-type: none"> - S. pneumoniae - H. influenzae - S. aureus - M. catarrhalis
--	---

www.microbiologynutsandbolts.co.uk

- Viruses are a common cause of respiratory tract infections, in over 25% of patients
- When caused by bacteria, exacerbation of COPD is usually caused by bacteria from the upper respiratory tract getting down in to the chest

Culture: classification of bacteria

Causes of LRTI usually originate in the upper respiratory tract

- The types of bacteria which commonly cause community acquired pneumonia usually originate from the upper respiratory tract
- Gram positive cocci
 - Streptococcus pneumoniae
 - Staphylococcus aureus
- Gram negative bacilli
 - Haemophilus influenzae
- Non-culturables ("atypicals")
 - Mycoplasma pneumoniae
 - Chlamydia pneumoniae
 - Legionella pneumophila
- Acid fast bacilli
 - Mycobacterium tuberculosis

Culture: how is sputum processed?

- Plated to mixture of selective and non-selective agar depending on clinical details
 - E.g. Cystic Fibrosis = *B. cepacia* agar
- Incubated for 48 hours before reporting
- Sensitivities take a further 24-48 hours
- Total time: 48-96 hours after receipt.

www.microbiologynutsandbolts.co.uk

- Most microbiological tests are based on the clinical information on the request card
- If adequate clinical information is not provided the correct tests may not be done e.g. if the request card does not say cystic fibrosis the lab will not look for *Burkholderia cepacia*
- In addition, clinical information allows the lab to spot high risk samples that may be hazardous to the health of the laboratory staff when they are processing them
- Sputum samples can take up to 96 hours to give a result which is only helpful in the event of either de-escalating antibiotics or knowing what to change to if the patient does not respond to initial treatment

Community Normal Flora

www.microbiologynutsandbolts.co.uk

- The normal flora of a human body consists of 10^{14} bacteria (that's approximately 15,000 times the number of humans on the Earth!)
- Knowing the common bacteria that colonise the human body allows:
 - Prediction of the causes of infection from any body site because 85% of infections are caused by the patient's own flora getting in to a site it should not be e.g. pneumonia caused by bacteria from the upper respiratory tract
- Prediction of the origin of an infection when a bacteria is found in a normally sterile site e.g. *E. coli* in blood cultures from either urine, bowel or Biliary tract

Antibiotics Change Normal Flora

www.microbiologynutsandbolts.co.uk

- The normal flora of a patient changes in hospital around 4 days after admission
- The upper respiratory tract becomes colonised with Gram-negative bacteria from the bowel
- This is the reason that different antibiotics are used to treat hospital acquired pneumonia (HAP) from community acquired pneumonia (CAP), NOT because one is more severe than the other
Note – it is also not correct to escalate from CAP antibiotics to HAP antibiotics because the causes are different and the antibiotics are chosen to treat these different antibiotics, they are different clinical conditions

Back to Mary...

- Sputum
 - Purulent
 - Culture Heavy Growth of *Moraxella catarrhalis*
 - Resistant to Amoxicillin & Clarithromycin
 - Sensitive to Co-amoxiclav & Doxycycline

How would you manage Mary now?

- Call to Mary, she was feeling much better and finished 7 days of Amoxicillin

Should she be given prophylactic antibiotics?

www.microbiologynutsandbolts.co.uk

- Although Mary has grown an organism resistant to the treatment she is on she is getting better and it is important to treat the patient not the result

Prophylactic Antibiotics

<p>Benefits</p> <ul style="list-style-type: none"> • ↓ frequency of exacerbations • Preservation of lung function • ↓ use of steroids 	<p>Potential Drawbacks</p> <ul style="list-style-type: none"> • Cautions and contraindications <ul style="list-style-type: none"> - e.g. macrolides and tetracyclines with myasthenia gravis • Allergies to antibiotics <ul style="list-style-type: none"> - ↓ choice for treatment • Side effects of the antibiotic? <ul style="list-style-type: none"> - e.g. Azithromycin and bone marrow and renal impairment • What monitoring of your patient do you have to do? <ul style="list-style-type: none"> - e.g. Azithromycin and FBC and U&Es • ↑ Antibiotic resistance
---	--

Problem: most studies on antibiotic prophylaxis do not look at long-term consequences

www.microbiologynutsandbolts.co.uk

- There is no proven role for prophylactic antibiotics in trying to prevent infections in COPD, essentially you would be trying to eliminate and control the upper respiratory tract flora and this is not meant to be sterile, all the antibiotics would do is make these bacteria more resistant

Jack

- 45 years old
- Presents with small pre-tibial laceration
- Ignored for few days now has slightly green slough
- Type 2 Diabetic
- Normal temperature, heart rate and blood pressure

How should Jack be managed?

www.microbiologynutsandbolts.co.uk

- As a diabetic Jack is particularly at risk of skin and soft tissue problems, including infection, ulceration and vascular insufficiency
- Green discolouration is often cited as evidence for the presence of *Pseudomonas aeruginosa*, and this is sometimes the case. *Pseudomonas* produces a chemical called pyoverdinin which is green and pyocyanin which is turquoise, leading to the greenish colour, however the presence of *Pseudomonas* does not necessarily mean there is an infection
- The correct management of Jack's ulcer would be to debride it and keep it clean

- Wound swab taken
- Started empirically PO Flucloxacillin 500mg QDS
- Advised to have daily dressing of wound with practice nurse
- 48 hours later not much change, switched to Erythromycin
- 96 hours after first consultation swab shows:
 - Mixed faecal flora
- Changed to PO Co-amoxiclav 625mg TDS
 - Wound swab repeated

Would you have done anything different?

www.microbiologynutsandbolts.co.uk

- Unfortunately Jack was given antibiotics despite having no evidence of infection
- The culture result is consistent with colonisation of the wound not infection, most wounds on the lower limb become colonised with bacteria that like warm moist sites, such as the enteric bowel flora
- The presence of bacteria does not necessarily indicate the need for antibiotics

- 1 week later reviewed wound still sloughy
- Repeat wound swab
 - Heavy growth of *Pseudomonas* sp. sensitive to Ciprofloxacin
- Patient changed to PO Ciprofloxacin 500mg BD

Would you do anything different?

www.microbiologynutsandbolts.co.uk

- Yet again Jack is given antibiotics despite no evidence of infection

- 2 weeks after initial injury
- Wound painful, surrounding erythema and increasingly purulent discharge

How are you going to manage Jack now?

www.microbiologynutsandbolts.co.uk

- Now Jack's ulcer is inflamed and infected
- At this stage antibiotics are indicated but given that he has had multiple different antibiotics in the recent weeks the chances of him having an infection with a nice sensitive bacteria are limited

Culture: how are wound swabs processed?

- Cannot do a Gram-stain
- Pus is always better!
- Mixture of selective and non-selective agar plates
- Culture 24-48 hours
- Sensitivities 24-48 hours
- Swab total time 48-96 hours
- A swab cannot diagnose an infection, that is a clinical judgement, it tells you what might be causing the infection.

www.microbiologynutsandbolts.co.uk

- The laboratory is often asked to do Gram stains on swabs but this is not a good idea as it contaminates the swab and rarely generates any meaningful results
- Pus on the other hand can be stained to give goods results
- It is one of the microbiology frustrations that surgeons will wash out litres of pus from an abscess but only send a swab to the lab... don't be this kind of doctor... put some pus in a sterile universal and send that to the lab instead

How to interpret a wound swab result?

- Appearance
 - Not available
- Microscopy
 - Not available
- Culture
 - Is the organism consistent with the clinical picture?

www.microbiologynutsandbolts.co.uk

- Wounds swabs can indicate the presence or absence of bacteria, but they cannot distinguish infection from colonisation, this is based upon the clinical picture
- Infection is the presence of inflammation and tissue damage caused by bacteria

Types & Causes of Bacterial Skin Infections

- Ulcers
 - *Staphylococcus aureus*, β -haemolytic *Streptococci*
 - Become colonised with bacteria, especially Enterobacteriaceae that DO NOT need treating in most patients
 - Take samples from "healthy" base after debriding slough
 - Only treat if increasing pain, erythema or purulent discharge
- Cellulitis
 - *Staphylococcus aureus*, β -haemolytic *Streptococci*

www.microbiologynutsandbolts.co.uk

- Most skin and soft tissue infections are caused by either *Staphylococcus aureus* or the Beta-haemolytic *Streptococci*

Culture: classification of bacteria

Skin infections are usually from direct inoculation or haematogenous spread

- Very occasionally bacteria such as *Pseudomonas aeruginosa* do cause serious infections of skin and soft tissue, but usually this is in the context of burns and skin grafts

Classification of Gram-positive cocci

www.microbiologynutsandbolts.co.uk

- Most skin infections are caused by Gram-positive cocci, notably *Staphylococcus aureus* and the Beta-haemolytic *Streptococci*
- Most microbiology text books list numerous biochemical tests to aid in distinguishing *Staphylococci* from *Streptococci* but these are of no use to ward doctors
- In practical terms Gram-positive cocci can be distinguished by:
 - *Staphylococci* form clumps
 - *Streptococci* form chains

Group	Members	Flora?	Colonial
A	<i>S. pyogenes</i> <i>S. pyogenes</i>	Mucosa, membranes?	Toxicity, cellulitis, septic arthritis, necrotising fasciitis
B	<i>S. agalactiae</i>	GI tract, genital tract (STIs)	Neonatal sepsis, septic arthritis, infective endocarditis, associated with meningitis?
C	<i>S. dysgalactiae</i> <i>S. equi</i> <i>S. equisimilis</i> <i>S. zooepidemicus</i>	Mucosa, membranes, arthritis?	Toxicity, cellulitis, septic arthritis
D	Enterococci faecalis, enterococcus faecium	GI tract	Infective endocarditis, IV catheter associated bacteraemia
E	"Hemolytic group" <i>S. thermophilus</i> <i>S. anginosus</i> <i>S. constellatus</i>	GI tract	Empyema (pleural and liver), bone infection and perforation
F	<i>S. faecalis</i>	Mucosa, membranes, bowel?	Toxicity, cellulitis, septic arthritis, associated with meningitis?

B-haemolytic Streptococci www.microbiologynutsandbolts.co.uk

- Beta-haemolytic Streptococcal grouping causes a lot of confusion but can be made simpler by considering different types together
- Beta-haemolysis refers to the type of red blood cell breakdown that the bacteria gives on blood agar in a laboratory, but there are 3 types of haemolysis
 - Alpha-haemolysis = partial haemolysis causing a green discolouration on blood agar (Viridans Streptococci, Viridans means green)
 - Beta-haemolysis = complete breakdown of the blood allowing you to see through the blood agar plate (see image in next slide)
 - Gamma-haemolysis = this is a very misleading term as in fact there is no haemolysis at all (also called non-haemolytic)
- Consider Groups A, C and G together because they all cause very similar infections of the upper respiratory tract, skin, bone and joint
- Consider Groups B, D and F together because they all originate in the gastrointestinal tract

Antibiotic Affect on Flora

Organism	Penicillins	Erythromycin	Co-trimoxazole	Ciprofloxacin
Streptococci	✓	✓	✓	✓
MRSA	✓	✓	✓	✓
MRSA	Resistant	Resistant	Resistant	Resistant
Enterobacteriaceae	Resistant	Resistant	✓	✓
Pseudomonas sp.	Resistant	Resistant	Resistant	✓
Multiple antibiotic resistant Gram negative bacteria	Resistant	Resistant	Resistant	Resistant

www.microbiologynutsandbolts.co.uk

- Knowing how antibiotics impact and influence the normal flora of the human body allows you to predict what is going to happen in a patient, and therefore if they do develop an infection, what the cause of that infection is
- In Jack, the multiple courses of unnecessary antibiotics he had will have selected out Meticillin resistant Staphylococcus aureus or resistant Gram-negative bacteria
- In the context of a skin and soft tissue infection the most significant of these is the MRSA, as Staphylococcus aureus is the most common cause of these types of infections

Back to Jack...

- Admitted to secondary care with established infection with MRSA cellulitis
- Blood cultures positive for MRSA
 - 20% mortality
 - National target ZERO preventable MRSA bacteraemias
- Fortunately made a full recovery after treatment with IV Teicoplanin for 2 weeks

Did Jack actually have an infection to begin with?
Could his later infection have been prevented?

www.microbiologynutsandbolts.co.uk

- As predicted Jack's infection was due to MRSA
- It is unlikely that Jack would have developed an infection if his normal flora wasn't adversely affected by the antibiotics he was given when he didn't have an infection

Betty

- 87 years old nursing home resident
- Presents with ↑ confusion and new incontinence
- On examination
 - Temperature 37.5 °C
 - Crackles throughout precordium
 - Cardiovascularly stable

How should Betty be managed?

www.microbiologynutsandbolts.co.uk

- There are many things that could be causing this problem in Betty, but the most common is a urinary tract infection
- It is reasonable to start her on a course of Trimethoprim or similar to cover for a simple UTI

- Likely urinary tract infection
- No systemic signs of evolving sepsis
- Treated for simple UTI with 3 days of Trimethoprim

www.microbiologynutsandbolts.co.uk

- It is reasonable to start her on a course of Trimethoprim or similar to cover for a simple UTI

- 2 days later not much better
- Still no systemic signs of evolving sepsis
- Check of recent bloods
 - eGFR >60ml/min
- Urine
 - Dipstick
 - Leucocytes ++, Nitrites ++
 - MSU (How do you take a proper MSU?) sent to lab
 - Microscopy

How would you manage Betty now?

- Started on second line Nitrofurantoin

www.microbiologynutsandbolts.co.uk

- At this stage it is sensible to take a midstream urine sample in order to check that Betty does not have an infection with a Trimethoprim resistant bacteria
- Urine point of care includes a dipstick test
 - Leucocytes indicate the presence of white blood cells and hence inflammation in the urinary tract
 - Bacterial nitrites are breakdown products from the action of bacteria on Urea and indicate the presence of bacteria
- Urine samples are prone to contamination so it is important to advise patients how to take a proper MSU
 - Part the labia or retract the foreskin, void the first part of the urine stream and discard, then catch the middle part of the stream.
 - The first part of the urine is prone to bacterial contamination from the urethra giving false positive results

How to interpret a urine result?

- Urine dipstick
 - Poor PPV, Good NPV
- Microscopy
 - White blood cells, red blood cells, epithelial cells
- Culture result
 - Is the organism consistent with the clinical picture?

www.microbiologynutsandbolts.co.uk

- As with other tests it is important to have a system for looking at microbiology results
- Urine dipsticks are good for excluding UTIs in normal immunocompetent adults but beware patients who cannot mount an immune response or who can have significant UTIs without a white blood cell response:
 - Neutropaenia
 - Pregnancy
 - Children
 - Anatomical abnormalities of the urinary tract
- Too many patients get treated for what is essentially normal flora and this is a mistake!

Microscopy of urine

- White blood cells
 - $>100 \times 10^6/L$ definitely significant
 - $>10 \times 10^6/L$ significant if properly taken MSU (rare!)
- Red Blood Cells
 - Poor correlation with UTI, used by urologist and renal physicians
- Epithelial cells
 - Indicator of contact with, and therefore contamination from, the perineum

www.microbiologynutsandbolts.co.uk

- A high WBC in the urine is consistent with a UTI but other systemic inflammatory conditions can give rise to pyuria e.g. pneumonia, appendicitis, etc
- The presence of epithelial cells in a urine sample indicates that the urine has not been taken correctly and has been in contact with the skin of the perineum with the risk that anything that has grown may actually be a contaminant from the perineal flora
- Positive bacterial culture in the presence of epithelial cells or the absence of white blood cells is consistent with possible contamination and should be regarded with caution when planning patient treatments (it may be better to repeat these samples with a carefully taken specimen)

Culture: how is urine processed?

- Day 1 Automated Microscopy
 - If values not significant, reported as negative
 - If values significant or specific patient group cultured with direct sensitivities
- Day 2
 - Reported with identification and sensitivities
- Patient groups always cultured
 - Cancer and haematology
 - Pregnant
 - Urology
 - Children < 5 years old

www.microbiologynutsandbolts.co.uk

- Most microbiological tests are based on the clinical information on the request card
- If adequate clinical information is not provided the correct tests may not be done e.g. if the request card does not say that the patient is pregnant then a full culture may not be performed
- In addition, clinical information allows the lab to spot high risk samples that may be hazardous to the health of the laboratory staff when they are processing them
- Most laboratories receive urine samples in boric acid containers which helps to stabilise bacterial growth and the white blood cell count for 24-48 hours before being tested however if less than about 8mls of urine is put in these containers then the concentration of boric acid may be high enough to actually kill the bacteria
 - If you are submitting a small volume sample e.g. from a child, use a normal sterile white universal and indicate this on the request form

2 days later

- Much more confused, still incontinent
- Very distressed
- Vomiting, diarrhoea
- Urine result
 - Microscopy $>100 \times 10^6/L$ WBC, no epithelial cells
 - Culture E. coli
 - Resistant to Amoxicillin, Co-amoxiclav, Trimethoprim, Cephredine, Ciprofloxacin
 - Sensitive to Nitrofurantoin
 - Further results to follow

How would you manage Betty?
What further results are to follow?

www.microbiologynutsandbolts.co.uk

- Betty's condition has clearly worsened, but why?
- It is easy to assume that she has developed a pyelonephritis or more severe UTI but there might be other reasons
- In this instance the E. coli is sensitive to Nitrofurantoin and so it is important to consider why the Nitrofurantoin is not working
- Nitrofurantoin is a pro-drug which is activated in the urinary tract, it is not systemically active
- In renal failure the pro-drug builds up in the blood stream causing toxicity, the symptoms of which are confusion, vomiting and diarrhoea
- The further test result to follow is a test for the reason why the bacteria are so resistant, and some further sensitivities

- Admitted to secondary care for IV antibiotics
- Started on Piptazobactam for sepsis, probably UTI
- Further result on MSU
 - E. coli ESBL positive

What is an ESBL?
What should Betty be treated with?
Why didn't Nitrofurantoin work?

www.microbiologynutsandbolts.co.uk

- An ESBL is an Extended-spectrum Beta-lactamase enzyme
- The most reliable antibiotic class for treating these resistant bacteria are the carbapenems such as Meropenem, Imipenem and Ertapenem
- The Nitrofurantoin didn't work because she was in renal failure but it wasn't noticed

Antibiotic dosing in renal failure

- Many antibiotics require dose reduction in renal failure
- eGFR is not an accurate predictor of renal function
- Use Cockcroft Gault equation
 - Actual body weight or Ideal Body Weight (IBW) if weight $> 20\%$ above IBW
 - Also use IBW for patients with oedema & ascites

www.microbiologynutsandbolts.co.uk

- Most antibiotics are affected in some way by renal failure
- Where doses are concerned it is important to use a calculated GFR because eGFR does not take body mass or even ethnic origin in to account and so can be very different from an actual value
- It is safest to use a calculated GFR to aid the prescribing of antibiotics in renal failure and to consultant renal dosing guidelines

How might weight effect Betty's GFR (ml/min)

Female, Age 87, Creatinine 75

Weight (kg)	eGFR	Calculated GFR	Variance
45	63	33	-30
50	63	37	-26
55	63	40	-23
60	63	44	-19
65	63	47	-16
70	63	51	-12
75	63	55	-8
80	63	59	-4

www.microbiologynutsandbolts.co.uk

- It is important not to overestimate the renal function of patients who are elderly and have little muscle mass
- In elderly patients, even relatively small changes in muscle mass can have profound effects on CrCl

Back to Betty...

- Started IV Meropenem 500mg BD
- 55kg, Creatinine 77
- Calculated GFR = 39 ml/min

www.microbiologynutsandbolts.co.uk

- Betty was started on the correct antibiotic at a reduced dose because she is in renal failure

48 hours later

- Much improved, diarrhoea and vomiting settled
- Bloods
 - WBC $19 \times 10^9/L$
 - CRP 198
 - U&Es - Urea 12, Creat 150
- Blood Culture
 - *Escherichia coli*, resistant to Amoxicillin, Co-amoxiclav, Gentamicin, Trimethoprim, Ciprofloxacin, Piptazobactam, Ceftriaxone (ESBL positive)
 - Sensitive to Meropenem, Amikacin

What should we do for Betty now?

www.microbiologynutsandbolts.co.uk

- Unsurprisingly, with correct treatment Betty improved and her Nitrofurantoin toxicity resolved
- Unfortunately there are no simple oral agents to treat this infection and Betty will require IV antibiotics to finish her treatment

- Continued IV Meropenem as no oral alternatives
- Given 7 days of antibiotics in total for severe UTI?
- Made a full recovery and went back to her nursing home

Warning – Betty is now known to be colonised with a Antibiotic-resistant E. coli so her future UTIs are likely to be resistant as well (it is part of her normal flora!)

www.microbiologynutsandbolts.co.uk

- It is likely that Betty has now changed her normal flora such that the predominant facultative anaerobic bacteria in her gut (E. coli) is resistant to many antibiotics
- Every time she develops an infection due to E. coli it is likely to be her own E. coli causing the problem, and this is now resistant to antibiotics
- This is going to lead to problems with choosing empirical therapy for infections in the future

Caution: Extended Spectrum Beta-lactamase

- Enzyme excreted into periplasmic space which inactivates antimicrobials by cleaving the β -lactam bond.
- Cause resistance to almost all β -lactams including 3rd-generation cephalosporins
- Associated with multiple antibiotic resistances
- Can be chromosome, plasmid or transposon encoded
- Can be constitutive or inducible
- Ideally patients with ESBLs should be managed in side-rooms with contact precautions

www.microbiologynutsandbolts.co.uk

- The extended-spectrum Beta-lactams are the 3rd generation cephalosprins such as Ceftriaxone, Cefotaxime and Ceftazidime
- These enzymes breakdown all of the commonly used Beta-lactams giving resistance to all except the carbapenems such as Meropenem, Imipenem and Ertapenem
- They can be associated with multiple resistance mechanisms
- Constitutive resistance is expressed all the time whereas inducible resistance is only expressed when induced by the presence of the antibiotic
 - Inducible resistance can be difficult to spot on laboratory tests and so a high degree of suspicion should exist when patients fail to respond to what appears to be effective treatment

Transfer of antibiotic resistance

The patient has Enterobacteria as part of their normal GI tract flora

The patient acquires an ESBL positive Enterobacteria via oral ingestion

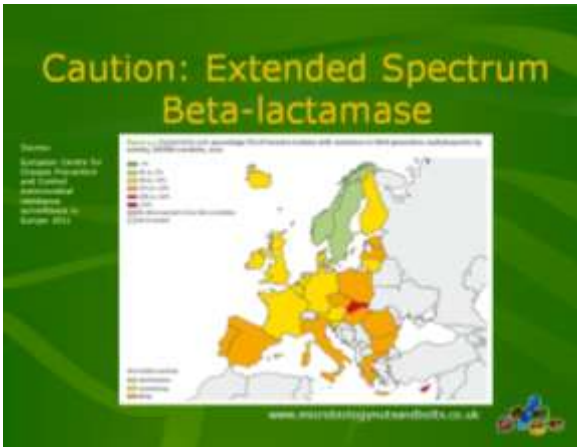

The ESBL can transfer on a plasmid to the Enterobacteria cell

The Enterobacteria cell in the UTI flora is now ESBL positive. If the patient then develops a UTI it is likely to be caused by an ESBL positive Enterobacteria cell

www.microbiologynutsandbolts.co.uk

- The genes encoding the production of ESBLs are usually carried on a mobile genetic element called a plasmid
- A plasmid is a circular piece of DNA that sits outside of the bacterial chromosome but which can be reproduced and transferred to other bacteria
- In this way antibiotic resistance can be spread from species to species, which is what has happened with ESBL-positive E. coli – the ESBL genes came from a different Gram-negative bacterial species called *Kluyvera* spp.

- The presence of ESBL positive bacteria is increasing worldwide with up to 10% of community E. coli isolates in UTIs now expressing the enzyme
- It is thought that the bacteria may be in the food chain and a number of specific sources have been proposed
- They represent a real public health threat and this is becoming the focus of Department of Health attention with regards to antibiotic resistance

The Future is Bleak

- Increasing numbers of Meropenem resistant Enterobacteriaceae in the UK from overseas
 - NDM-1 = New Delhi Metallo-beta-lactamase
 - KPC = Klebsiella pneumoniae carbapenemase
- Now starting to see Amikacin resistance as well
- Only antibiotic left is Colistin
 - 60+ years old
 - Some bacteria are known to be inherently resistant (Proteus sp., Serratia sp.)
 - May become transferable and then have a real "superbug" for the post-antibiotic era...

www.microbiologynutsandbolts.co.uk

- Antibiotic resistance is an increasing problem for healthcare
- There are no new antibiotics being developed against Gram-negative bacteria, and we have only just seen the first new class of antibiotic discovered within the past 30 years (Teixobactin)
- Antibiotic development is not cost effective for pharmaceutical companies, short courses of restricted medications makes them expensive, and then hospitals won't use them
- Something needs to change...

Conclusions

- 3 clinical scenarios showing some of the pitfalls in managing apparently simple infections
- Look at microbiology results in order
 - Appearance, Microscopy and Culture
- There are significant benefits to antibiotics but increasingly there are also dangers
- Conflict of medicine moving to 1^o care but infections moving to 2^o care – need for OPAT
- The future is looking bleak, we need to try and preserve what we have for as long as we can...

www.microbiologynutsandbolts.co.uk

- A knowledge of clinical microbiology can significantly benefit your patients
- Prescribing antibiotics is not completely without risk, and these should be weighed against the potential benefits to the patient
- OPAT = Outpatient Parenteral Antibiotic Therapy, the giving of intravenous antibiotics in an outpatient setting for infections, with the same standard as given for inpatients
