

Microbiology Nuts & Bolts: Session 1: Respiratory

Aims & Objectives

- To know how to diagnose and manage life-threatening infections
- To know how to diagnose and manage common infections
- To understand how to interpret basic microbiology results
- To have a working knowledge of how antibiotics work
- To understand the basics of infection control

www.microbiologynutsandbolts.co.uk

- 30-40% of patients admitted to hospital will receive an antibiotic
- It is critical to pick out those with life-threatening conditions in order to manage them appropriately and correctly in order to give them the best chance of survival
- It is also important to know how to diagnose and manage common infections so that complications do not occur and patients get better as quickly as possible
- Knowing about antibiotics ensures the correct ones are used for the correct indications, prevents prescribing errors and keeps patients safe
- Everyone working in a healthcare setting has a responsibility to protect patients from harm including cross infection from other patients

Mary

- 70 years old
- Presents with fever & shortness of breath
- On examination
 - Temperature 38.5 °C
 - Decreased air-entry at the right base
 - B.P. 140/85
- How should Mary be managed?

www.microbiologynutsandbolts.co.uk

- A vague history but allows the process of diagnosing the patient to begin
- There are non-infectious reasons for fever and shortness of breath therefore it is important not to become too fixated on a diagnosis without considering all possibilities
- All doctors should know the limitations of the tests they do including basic observations not just laboratory tests
- Normal temperature is 36.5°C to 37.5°C
 - Often a tympanic temperature which is actually a peripheral temperature not a core temperature
 - Can vary from core by up to +/- 1°C
 - Works by infrared looking at the tympanic membrane therefore any obstruction in the ear can lead to a false temperature result
- Decreased air entry is more in keeping with either fluid or collapse of the lung than infection which when giving rise to consolidation leads to bronchial breathing (a harsh breath sound)
- One off values of blood pressure can be valuable if very abnormal but trends are usually more informative and knowing if the patient is normally hypo/hypertensive (helps to look at the medications)
- After emergency care (ABC) the next step is to take a full history and perform an examination in order to produce a differential diagnosis

Questions to ask yourself...

- What urgent care does she need?
- Does she have an infection?
- What is the likely source of infection?
- What are the likely causes of the infection?
- Have you got time to pursue a diagnosis or do you need to treat her now?
- How are you going to investigate her?
- When will you review her?

All of the above is based on your differential diagnosis

www.microbiologynutsandbolts.co.uk

- If Mary is septic then she needs urgent care, for every hour delay in giving effective treatment the mortality increases by 7% up to approximately 40% by 6 hours
- If she is very unwell then she will need frequent and regular review in order to ensure she is improving or to spot any deterioration as early as possible
- The differential diagnosis is a list of possible reasons for a patient's illness which can then be narrowed down through careful questioning, examination and investigation until a single unifying diagnosis is proven

Microbiology Nuts & Bolts: Session 1: Respiratory

- Formulating a differential diagnosis appears to be going out of fashion but it is essential if diagnoses are not to be missed
- A systems approach (e.g. respiratory, cardiac, Gastrointestinal, genitourinary, neurological, skin, bone, joint, etc) can be fitted to a template of life-threatening, common, uncommon in order to complete the differential but considering the life-threatening first ensures these are dealt with as early as possible
- It is not a static process but can change throughout a patients management as new information becomes available and their clinical condition changes

- The list represents a common “septic screen” within the hospital setting to which could be added a lumbar puncture if a neurological diagnosis was possible
- The history is the most important aspect where infection is concerned but it is a skill that has to be learnt and practiced to become good at it
- It is essential to know the normal values of all tests within your hospital
- Full blood count (FBC)
 - The total white blood cell count can go up or down in infection
 - The differential white blood cell count can help to point to the type of organism but nothing is 100% (neutrophils = bacteria/fungi, lymphocytes = viruses, eosinophils = parasites)
 - Platelets are an acute phase reactant and go up in infection (they can go down in severe infections when disseminated intravascular coagulation DIC develops)
- CRP (C reactive protein)
 - Produced in liver in response to inflammation, often goes up in bacterial infection
 - >200 usually significant, otherwise need to know what the trend is i.e. increasing, decreasing
 - Beware, patients in liver failure do not produce much CRP – use other markers of liver synthetic function to guide you e.g. INR, Albumin
- Urea & Electrolytes (U&Es)
 - Antibiotics can only be prescribed safely if the patients kidney function is known
 - Urea and Creatinine can be markers of severity of infection e.g. Urea in community acquired pneumonia and creatinine in Clostridium difficile
- Chest X-ray is required by the British Thoracic Society in order to diagnose pneumonia in hospital

Microbiology Nuts & Bolts: Session 1: Respiratory

- Bloods
 - WBC $22 \times 10^9/L$
 - CRP 313
 - U&Es - Urea 17, Creat 157
- Urine
 - Dipstick - leuca, - nitrites
 - Microscopy $<10 \times 10^6/L$, WBC, no epithelial cells
- Sputum
 - Mucoid appearance
 - Gram stain Gram-positive cocci in chains
- How would you manage Mary now?

- Patient has an inflammatory process going on with high white blood cells and CRP
- U&Es shows a degree of renal failure and if this patient has pneumonia then the U of CURB-65 is fulfilled with a urea $> 7\text{mmol/L}$
- The urine has no leucocytes or bacterial nitrites which has a high negative predictive value of 97%, i.e. the patient does not have a UTI
 - The absence of squamous epithelial cells also suggests the urine has not been in contact with the skin of the perineum making contamination less likely
- It is important to have a system for looking at Chest X-rays, one such system is:
 - Most obvious abnormality first
 - A = Airways and lungs including hilum
 - B = Bones
 - C = Cardiac outline and blood vessels
 - D = Diaphragm and air under it
 - E = Everything else including lines, NG tubes, ETT tubes etc
- This X-ray shows right basal consolidation

Appearance of sputum

- Salivary
 - Spit not phlegm, risk of contamination
- Mucoid
 - Upper respiratory tract specimen, no evidence of inflammation
 - Beware neutropenic patients
- Purulent
 - Pus, indicates inflammation not infection
- Blood stained
 - May indicate infection but not pathogenic

- As with other tests it is important to have a system for looking at microbiology results
- Microbiology results should be looked at in the following order if available:
 - Appearance
 - Microscopy
 - Culture
- For sputum results the appearance gives guidance on the likelihood of any cultured bacteria being from the upper respiratory tract or not
- Too many patients get treated for what is essentially normal flora and this is a mistake!

Culture: classification of bacteria

Causes of pneumonia usually originate in the upper respiratory tract

- The types of bacteria which commonly cause community acquired pneumonia usually originate from the upper respiratory tract
- Gram positive cocci
 - Streptococcus pneumoniae
 - Staphylococcus aureus
- Gram negative bacilli
 - Haemophilus influenzae
- Non-culturable ("atypicals")
 - Mycoplasma pneumoniae
 - Chlamydia pneumoniae
 - Legionella pneumophila
- Acid fast bacilli
 - Mycobacterium tuberculosis

Microbiology Nuts & Bolts: Session 1: Respiratory

Classification of Gram-positive cocci

- Most microbiology text books list numerous biochemical tests to aid in distinguishing Staphylococci from Streptococci but these are of no use to ward doctors
- In practical terms Gram-positive cocci can be distinguished by:
 - Staphylococci form clumps
 - Streptococci form chains

Culture: how is sputum processed?

- Plated to mixture of selective and non-selective agar depending on clinical details
 - E.g. Cystic Fibrosis = B. cepacia agar
- Incubated for 48 hours before reporting
- Sensitivities take a further 24-48 hours
- Total time 48-96 hours after receipt.

- Most microbiological tests are based on the clinical information on the request card
- If adequate clinical information is not provided the correct tests may not be done e.g. if the request card does not say cystic fibrosis the lab will not look for Burkholderia cepacia
- In addition, clinical information allows the lab to spot high risk samples that may be hazardous to the health of the laboratory staff when they are processing them
- Sputum samples can take up to 96 hours to give a result which is only helpful in the event of either de-escalating antibiotics or knowing what to change to if the patient does not respond to initial treatment

Community Normal Flora

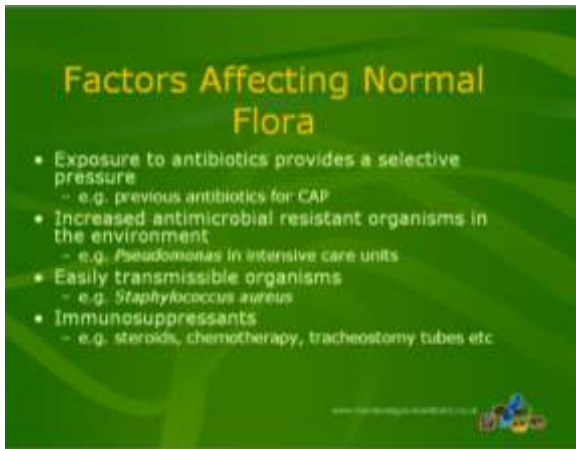

- The normal flora of a human body consists of 10^{14} bacteria (that's approximately 15,000 times the number of humans on the Earth!)
- Knowing the common bacteria that colonise the human body allows:
 - Prediction of the causes of infection from any body site because 85% of infections are caused by the patients own flora getting in to a site it should not be e.g. pneumonia caused by bacteria from the upper respiratory tract
 - Prediction of the origin of an infection when a bacteria is found in a normally sterile site e.g. E. coli in blood cultures from either urine, bowel or Biliary tract

Microbiology Nuts & Bolts: Session 1: Respiratory

- The normal flora of a patient changes in hospital around 4 days after admission
- The upper respiratory tract becomes colonised with Gram-negative bacteria from the bowel
- This is the reason that different antibiotics are used to treat hospital acquired pneumonia (HAP) from community acquired pneumonia (CAP), NOT because one is more severe than the other
 - Note – it is also not correct to escalate from CAP antibiotics to HAP antibiotics because the causes are different and the antibiotics are chosen to treat these different antibiotics, they are different clinical conditions

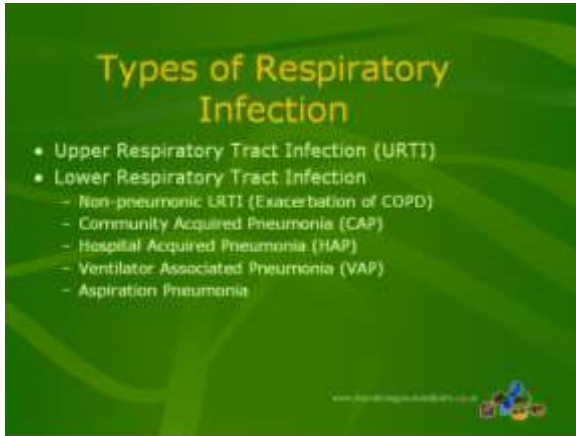

- There are many circumstances that can affect a patient's normal flora
- Understanding how this happens can allow predictions to be made as to how the flora will change and therefore how this will influence the types of bacteria causing infections
- Antibiotics will tend to remove sensitive bacteria from the flora leaving the resistant ones behind, for this reason if antibiotics have been used as prophylaxis for a procedure any infection occurring immediately after the procedure is likely to be resistant to those antibiotics

- The chest X-ray proves a diagnosis of Community Acquired Pneumonia
- Whilst *Streptococcus pneumoniae* is one of the most common bacterial causes of pneumonia it is also part of the normal flora of the upper respiratory tract and therefore if this is a heavy growth in a purulent sample it is likely to be the cause of the pneumonia, otherwise it could be a contaminant
- Mary's treatment would be based upon an assessment of her CURB-65 score:
 - C = Confusion (new onset)
 - U = Urea $>7 \text{ mmol/L}$
 - R = Respiratory Rate $>30/\text{min}$
 - B = Blood pressure $<90 \text{ mmHg}$ systolic or $\leq 60 \text{ mmHg}$ diastolic
 - 65 = Age >65 years
 - A CURB-65 score of 3 or more is considered severe

Microbiology Nuts & Bolts: Session 1: Respiratory

Types of Respiratory Infection

- Upper Respiratory Tract Infection (URTI)
- Lower Respiratory Tract Infection
 - Non-pneumonic LRTI (Exacerbation of COPD)
 - Community Acquired Pneumonia (CAP)
 - Hospital Acquired Pneumonia (HAP)
 - Ventilator Associated Pneumonia (VAP)
 - Aspiration Pneumonia

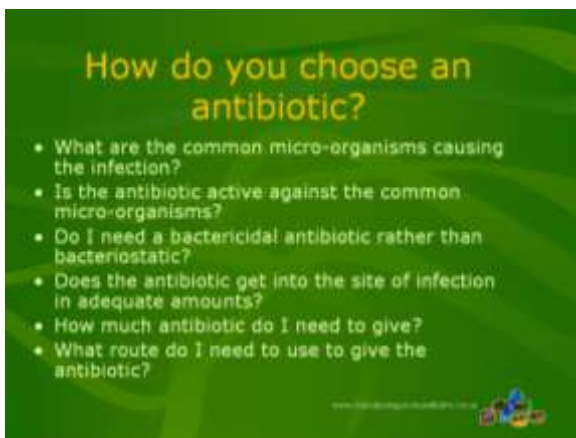

- There are a number of different definitions for respiratory infections.
- CAP = pneumonia occurring in the community or within 48 hours of admission to hospital
- HAP = pneumonia occurring more than 48 hours after admission to hospital AND not incubating at the time of admission
- The incubation comment in HAP is because some causes of CAP have incubation periods of up to 10 days e.g. Legionella pneumophila

Do patients need antibiotics?

- Some bacterial infections do not need antibiotics e.g. urethral syndrome, gastroenteritis
- Viruses do not respond to antibacterials!
 - However there are antivirals e.g. aciclovir, oseltamivir etc.
- There are many non-infection reasons for "signs" of infections e.g. pyuria, raised CRP, crackles in the chest etc
- The presence of bacteria does not necessarily mean there is an infection!
 - Bacteria colonise, such as upper respiratory tract, surgical wounds, ulcers

- Over treatment with antimicrobials is a common and serious problem
- There are a number of common reasons for this:
 - The patient does not have a bacterial infection
 - Clinical signs are over interpreted
 - Treatment is trying to target normal flora
- Many of these instances can be avoided by carefully considering the patient and their results before deciding to treat

How do you choose an antibiotic?

- What are the common micro-organisms causing the infection?
- Is the antibiotic active against the common micro-organisms?
- Do I need a bactericidal antibiotic rather than bacteriostatic?
- Does the antibiotic get into the site of infection in adequate amounts?
- How much antibiotic do I need to give?
- What route do I need to use to give the antibiotic?

- It is important to understand why different antibiotics are used to treat different types of infections
- It is dangerous to follow guidelines blindly without considering how these guidelines have been produced because mistakes can be made for the few patients whose clinical situation lies outside those guidelines e.g. the guideline says an oral antibiotic but the patient is unable to absorb from their gastrointestinal tract

Microbiology Nuts & Bolts: Session 1: Respiratory

In reality...

see list of general guidelines

www.microbiologynutsandbolts.co.uk

- Empirical antibiotic guidelines vary a little between hospitals based upon local epidemiology, therefore it is important to know your own guidelines
- They are empirical, that is they are designed to initiate treatment when the cause is unknown, they are not definitive for a specific cause
- Once the cause of an infection is known the antibiotics should be changed to specifically target that infection, the guidelines have done their job by that time and are no longer required

Chromosomes

- Quinolones (e.g. Ciprofloxacin, Levofloxacin) inhibit DNA Coiling
- Nitroimidazole (Metronidazole) inhibits DNA polymerase

Ribosome

- Macrolides (e.g. Erythromycin, Clindamycin, Azithromycin) prevents protein elongation and inhibits ribosome formation
- Tetracyclines (e.g. Doxycycline) prevents protein synthesis

Cell Wall

- Beta Lactams (e.g. Penicillins) inhibit cell wall formation

www.microbiologynutsandbolts.co.uk

- The mechanisms of action of antibiotics causes a lot of confusion (and the similarity of names makes it even worse – anything ending in “mycin” is derived from a fungus and has nothing to do with the class of the bacteria!)
- It can helpful to split them into groups as this at least reduces the list to a more manageable size:
 - Mainly act on the cell wall
 - If no cell wall or unable to penetrate Gram-negative cell membrane to cell wall then no activity i.e. glycopeptides have no Gram-negative activity
 - Mainly act on the ribosome
 - Interfere with protein production therefore may not be cidal to some bacteria
 - Mainly act on the chromosome
 - Quinolones interfere with DNA coiling and are broad spectrum and cidal, however there is some evidence that they promote mutation and therefore resistance in bacteria

Other considerations when choosing antibiotics

- Are there any contraindications and cautions?
 - e.g. macrolides and quinolones with myasthenia gravis
- Is your patient allergic to any antibiotics?
 - e.g. β -lactam allergy
- What are the potential side effects of the antibiotic?
 - e.g. Doxycycline and light hypersensitivity reactions
- What monitoring of your patient do you have to do?
 - e.g. β -lactam and liver function

www.microbiologynutsandbolts.co.uk

- Myasthenia gravis is a contra-indication to many antibiotics so if your patient has this then check in the British National Formulary (BNF) or with a pharmacist before prescribing
- Mild Beta-lactam allergy occurs in 1 in 20 patients, however severe is rare, only in 1 in 2000 patients
- Some antibiotics have common or severe side effects and doctors should be familiar with these and warn patients about them, as part of the informed consent to treatment process
- Many antibiotics also require monitoring for these side effects and this should be checked in the BNF at the time of prescribing

Microbiology Nuts & Bolts: Session 1: Respiratory

Mary

- CURB 65 Score 3
- Started on IV Co-amoxiclav and Clarithromycin

www.microbiologynutsandbolts.co.uk

- The antibiotics cover the possible infective bacteria:
 - Co-amoxiclav – Streptococcus pneumoniae, Haemophilus influenzae, Staphylococcus aureus
 - Clarithromycin – Mycoplasma pneumoniae, Chlamydia pneumoniae, Legionella pneumophila

Next Day

- Worsening respiratory function
- Bloods
 - WBC $22 \times 10^9/L$
 - CRP 375
 - U&Es - Urea 18, Creat 178
- Urine
 - Microscopy < 10 WBC, no epithelial cells
 - Culture - No growth
- Blood Culture
 - Gram-positive coccus clumps
- Would you do anything different for Mary now?

www.microbiologynutsandbolts.co.uk

- Patients take time to respond to antibiotics and therefore it is usually not necessary to broaden up cover early
- A common mistake is to “escalate” to HAP antibiotics thinking these are better but this usually involves losing the cover for the non-culturable bacteria
- The blood culture in this instance will be a Staphylococcus, and the majority of these are skin contaminants (Coagulase negative Staphylococci)
 - Most laboratories telephone out all positive blood cultures

- Discussed with Consultant Microbiologist
- Advised to continue current antimicrobial therapy
- Given Non-invasive ventilatory support

www.microbiologynutsandbolts.co.uk

- It is important to remember that antibiotics are not the only treatment for pneumonia, and many hospitalised patients require some form of respiratory support
- Non-invasive ventilatory support essentially means she did not require mechanical ventilation

Microbiology Nuts & Bolts: Session 1: Respiratory

Day 3

- Much improved
- Bloods
 - WBC $19 \times 10^9/L$
 - CRP 198
 - U&Es - Urea 12, Creat 150
- Blood Culture
 - Coagulase negative staphylococcus
- Would you do anything different for Mary now?

- At this stage Mary has shown improvement and a decision should be made about switching her antibiotics from IV to oral
- This is better for the patient in terms of reducing the risk of IV device associated infections and can also facilitate discharge from hospital
- The blood culture is confirmed as a skin contaminant

- Switched to oral co-amoxiclav and clarithromycin
- How long will you treat her for in total?
- Mary given 7 days total antibiotics and made a full recovery

- The treatment for CAP is usually 7 days
- It is important to remember that the patient is unlikely to be back to normal at this and they may still have an abnormal chest X-ray however this is not usually due to ongoing infection but rather the inflammation and damage caused by the infection which may take longer to heal

Caution: *Mycobacterium tuberculosis*

- 9000 new cases per year reported in UK
 - Additional 80,000 asymptomatic
- Delayed diagnosis puts healthcare workers at risk
- Treatment
 - Quadruple therapy (Rifampicin, Isoniazid, Ethambutol & Pyrazinamide)
 - Duration 6 months
- TB should be managed in a side-room

- Tuberculosis (TB) used to be the third most common cause of death in the UK
- Most patients are asymptomatic however it has been estimated that each untreated person can infect up to 10-15 other people so it is important to diagnose as many as possible
- Many of the patients diagnosed in the UK were born in, or have contact with people from, countries where TB is endemic
- Treatment should be guided by a physician experienced in managing patients with TB because side-effects can occur and compliance can be an issue
- Patients with TB should be managed in a side-room in hospital until they have received at least 2 weeks of treatment or had 3 negative sputum smears for TB

Microbiology Nuts & Bolts: Session 1: Respiratory

- Multi-drug resistant TB (MDR TB) is resistant to Isoniazid and Rifampicin
 - Treatment requires the use of other cidal agents such as the fluoroquinolones and the aminoglycosides
- Extensively Drug Resistant TB (XDR TB) is resistant to Isoniazid, Rifampicin, fluoroquinolones and Aminoglycosides
 - Treatment is difficult and the mortality is high
 - This requires specialist facilities and experience to treat safely
- If we were to go back to the days when we had no antibiotics for TB then we would see approx. 36,000 deaths/year in the UK (currently 250 deaths per year)!

Conclusions

- Pneumonia is usually caused by bacteria from the upper respiratory tract
 - *Streptococcus pneumoniae*
 - *Staphylococcus aureus*
 - *Haemophilus influenzae*
 - Non-culturable
- The normal flora of the upper respiratory tract changes in hospital and so the causes of pneumonia change
- Antibiotics are chosen to treat the likely bacteria
- All of the microbiology report is important and helps with interpretation of the result
- If you don't consider tuberculosis you will miss it...

- Pneumonia is a common diagnosis in hospitals
- In order to diagnose and manage it effectively it is important to understand:
 - The common causes
 - The limitations of the investigative tests used
 - The choice of antibiotics
 - The risk of the cause being something not covered by the common treatments

More information on respiratory infections is available in the pocket guide Microbiology Nuts & Bolts by Dr David Garner
